### Abstract

Measurements of the short distance "hard" scattering process are neither good enough to perform precise standard model measurements nor in the search for new phenomena. The analysis of the data from the *underlying events* is done in order to understand the process better. Three regions are defined on the basis of the azimuthal angle from the leading track, and the relative angle distributions are found. For each region and particle multiplicity, the scalar sum of transverse momentum and average density of charged particles are analyzed. This report encapsulates the aforementioned analysis in the form of histogram plots which facilitate visual inspection of the data.

# 1 Introduction

The data was generated from the interactions of protons in proton-proton collisions (p-p collision) at 13TeV using the Pythia 8 Monte Carlo event generator and were provided by the team at ATLAS

These interactions are collectively referred to as underlying events (UE). The UE observables are constructed from the primary charged particles in the *pseudorapidity* range, i.e.,  $|\eta| < 2.5$ .

The particles are observed as *tracks* in the detector and the *leading track* is the direction of the track along the parallel of the particle with highest  $p_T$ . This track, which will be referred to as  $p_T^{Lead}$ , is used as a reference for the  $\eta - \phi$  plane.

The number of particles emitted in each event or entry, is given by the particle multiplicity, and in this report, we discuss about 3 multiplicity classes, 0 to 20, 20 to 40 and 40 to 60.

Figure 1: Definition of regions in the azimuthal angle with respect to the leading track [1]

Variables	Definition
$p_T$	Transverse momentum of the particle (component of momentum perpendicular to $z$ axis)
$\theta$	Angle between momentum vector and $z$ axis
$\phi$	Azimuthal angle
$\eta$	Pseudo-rapidity of the particle defined as $\ln(\cot(\theta/2))$
$p_T^{lead}$	Transverse momentum of the stable charged particle with maximum $p_T$ in the event
$\langle d^2 N_{ch}/d\eta d\phi \rangle$	Mean number of stable charged particles per unit $\eta - \phi$
$\langle d^2 \sum p_T/d\eta d\phi \rangle$	Mean scalar $p_T$ sum of stable charged particles per unit $\eta - \phi$

## 2 Observations

### 2.1 Plots of frequency vs $\Delta\phi$

The normalized frequencies of the relative angle between the particle with  $p_T^{lead}$  and other particles are plotted here in a specific manner for all entries. It has been implemented by iterating a *loop* to find the particle with lead  $p_T$  and then a function to calculate the relative angle of all other particles, in the range 0 to  $\pi$ , with respect to the leading particle and filled these values in a histogram. The lead  $p_T$  has been excluded using a conditional statement to avoid the case where  $\Delta\phi$  is 0.

The figures 2,3 and 4 are the 1-D Histograms of  $\Delta\phi$  for the multiplicity classes as given in the plots.

Figure 2:  $\Delta\phi_{020}$

Figure 3:  $\Delta\phi_{2040}$

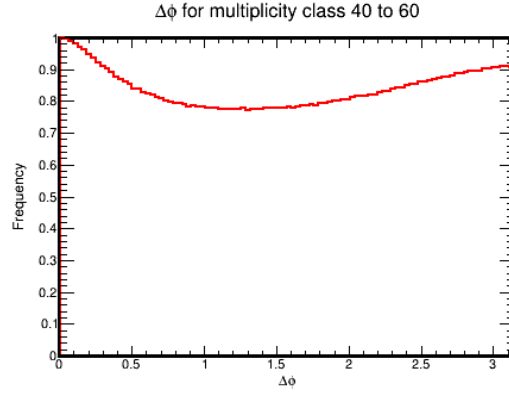

Figure 4:  $\Delta\phi_{4060}$

## 2.2 Plots of density of charged particles emitted as a function of $p_T^{lead}$

Reiterating the point under introduction, each entry has particles emitted in the toward, away and transverse region with respect to the particle with transverse momentum  $p_T^{lead}$ . To implement this, the leading track was found, and the relative angle of all particles with respect to the leading one were calculated. For each region, a  $\Delta\phi$  cutoff was provided, and the number of particles in that region were calculated and scaled by a factor  $\frac{3}{5\pi}$ . The mean of the resulting 2-D Histogram of  $p_T^{lead}$  and  $N$  was calculated using a *TProfile* class.

Figures 5,6 and 7 represent the scaled density of charged particles for multiplicity class 0 to 20, for the regions Toward, Transverse and Away respectively.

Figure 5:  $\frac{d^2 N_{ch}}{d\eta d\phi}_{020T}$

Figure 6:  $\frac{d^2 N_{ch}}{d\eta d\phi}_{020T}$

Figure 7:  $\frac{d^2 N_{ch}}{d\eta d\phi}$  020A

Figures 8,9 and 10 represent the scaled density of charged particles as a function of  $p_T^{lead}$  for multiplicity class 20 to 40, for the regions Toward<sup>1</sup>, Transverse and Away respectively.

Figure 8:  $\frac{d^2 N_{ch}}{d\eta d\phi}$  2040F

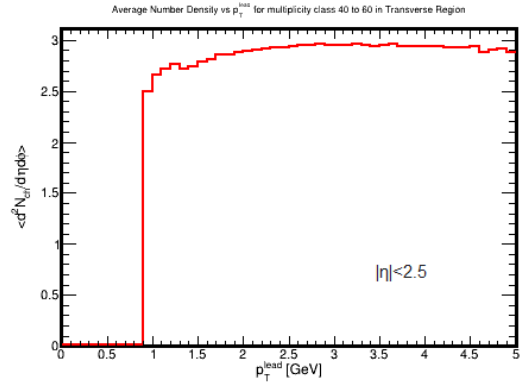

Figure 12:  $\frac{d^2 N_{ch}}{d\eta d\phi}$  4060T

Figure 13:  $\frac{d^2 N_{ch}}{d\eta d\phi}$  4060A

### 2.3 Plots of scalar $\sum p_T$ density of the charged particles as a function of $p_T^{lead}$

Here, the scalar sum of  $p_T$  over all the particles in a particular region has been found. To implement this, data regarding the leading track and the relative angle of all particles with respect to the leading one were used again. For each region, a  $\Delta\phi$  cutoff was provided, and the scalar sum of transverse momenta for particles in that region were calculated and scaled by a factor  $\frac{3}{5\pi}$ . The mean of the resulting 2-D Histogram of  $p_T^{lead}$  and  $\sum p_T$  was calculated using a *TProfile* class.

Figures 14, 15 and 16 represent the scaled scalar  $\sum p_T$  as a function of  $p_T^{lead}$  for multiplicity class 0 to 20, for the regions Toward, Transverse and Away respectively.

Figure 14:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  020F

Figure 15:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  020T

Figure 16:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  020A

Figures 17, 18 and 19 represent the scaled scalar  $\sum p_T$  as a function of  $p_T^{lead}$  for multiplicity class 20 to 40, for the regions Toward, Transverse and Away respectively.

Figure 17:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  2040F

Figure 18:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  2040T

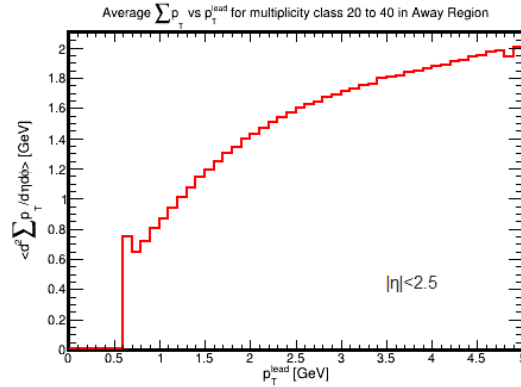

Figure 19:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  2040A

Figures 20, 21 and 22 represent the scaled scalar  $\sum p_T$  as a function of  $p_T^{lead}$  for multiplicity class 40 to 60, for the regions Toward, Transverse and Away respectively.

Figure 20:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  4060F

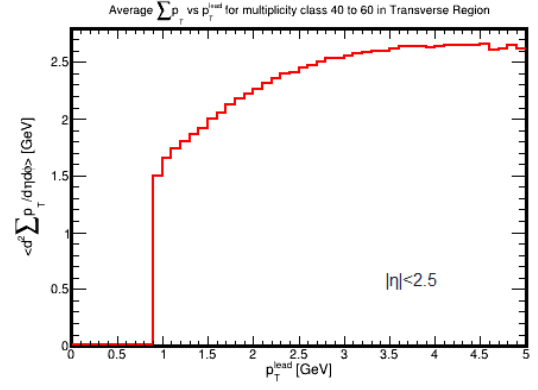

Figure 21:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  4060T

Figure 22:  $\frac{d^2 \sum p_T}{d\eta d\phi}$  4060A

### 3 Summary

The data from the accompanying interactions of proton-proton collisions were analysed using ROOT, an object-oriented program and first-party library developed by CERN, over various multiplicity classes and directions of momenta. The methodology involved classifying the events based on the azimuthal angle with respect to axis defined by the leading track and the speed of the particle, given in the form of its rapidity. This study was carried out for over 2 million such events and the final results were plotted for the different multiplicity classes. In the first subsection, the frequency histogram of the relative angles subtended by particles with respect to the leading particle was plotted. The density of these emitted charged particles were plotted as a function of the momentum of the leading particle under the second subsection, while the density of the scalar sum over the momenta of particles were plotted against the leading particle momentum as the final subsection. All the figures used, results obtained and the codes have been documented [here](#).
